Europe in the AI network: pitch speech

Group F · Applied Network Analysis · 2 Nov 2026 · about 1 minute per presenter

1. Cover

Cintia · about 5 seconds

Hi, we're Group F: Ifeoluwa, Sofiia, Ella and me, Cintia. Our project is Europe in the AI network.

2. What is the network?

Cintia · about 55 seconds

Every AI app is built on other things. A model is trained on datasets, and an app is built on a model. So AI has a supply chain. An AI app is assembled from models and data made by many groups. Researchers call this the foundation model supply chain and draw this supply chain as a network. Our nodes are models, datasets and apps. A link from A to B means A is used to build B. For example, the dataset The Pile was used to build the model GPT-NeoX, which was used to build the GooseAI API. Why do we care? We use AI apps every day, but the chain behind them is hidden. A few hubs in that chain can shape much of what is built on top of them. We want to understand where Europe sits in this network: what it builds on, and what others build on it. Now Ifeoluwa will explain how we collect the data.

3. How do we collect the data?

Ifeoluwa · about 1 minute

Our data comes from Ecosystem Graphs, a public project by Stanford researchers, Bommasani and colleagues, 2024. They document AI models, datasets and apps, and record what each one was built from. The records are public on GitHub. We downloaded them and froze one release, so our numbers don't change. Each record becomes a node, and each "built from" entry becomes a link. Things that are used but not documented, like Wikipedia, we added as outside sources. Then we cleaned the names, so nothing is counted twice. Each node keeps its type, organisation, date, access and licence. The organisation is what lets us answer the Europe question. Sofiia will now tell you how big the network is.

4. How big is it?

Sofiia · about 1 minute

Our network has 742 nodes and 751 links, well above the 100 nodes we need. 359 are models, 112 datasets, 97 apps, and 174 outside sources. The links are directed, from what is used to what is built. The data covers AI up to April 2024. To estimate the size today, we used the network's growth over its last 12 months. At that rate, it would now have about 1,600 to 3,400 nodes and 1,600 to 4,900 links. So the real network is bigger than what we see, and we keep that in mind when we read our results. Ella will present our questions.

5. What will we ask?

Ella · about 1 minute

We have four questions. First, who does Europe build on? We will tag each of the 194 organisations by region, such as EU, US, China or other, and follow the links into European models and apps. Second, the other direction: who builds on European models and data? Third, which hubs hold the network up? We find them with centrality. Then we remove the biggest hubs one at a time, and see how much of the network, and of European AI, stays connected. Fourth, how did this change from 2019 to 2024? We compare every result with a random network of the same size, so we know what is really surprising. That's our project. Thank you!
